From tests to models

Objectives

- Demystifying data modelling
- Showing that modelling is more understandable than tests
- Showing that we often model without knowing it
- Moving to Bayesian models

Approach

- Unpacking a simple ANOVA
- Showing that ANOVA is a linear model* in disguise
- Running a first Bayesian model

* Technically is a method applied to a linear model

Are the means different?

How can we answer this question?

Frequentist	ANOVA Linear Moel
Bayesian	General Linear Model

How can we answer this question?

Frequentist	ANOVA Linear Moel
Bayesian	General Linear Model

Argument:

a) ANOVA and Linear Model are equivalent
b) Linear models are more flexible than standard tests
c) Bayesian models offer more information than frequentists linear models
d) Then: we should opt for Bayesian models

Steps

1. Load data
2. Compute participants' and conditions' averages
3. Compute Variance Metrics
4. Get F-statistics
5. Working on p-value

NOTE: The code needs to be adjusted (do not rush through)

Why Variance

- Why do we use analysis of variance to test a difference in means?

Why Variance

- Why do we use analysis of variance to test a difference in means?

If variance between groups is higher than variance within groups, then the observations are likely drawn from two different distributions

Why Variance

- Why do we use analysis of variance to test a difference in means?

Otherwise, it's **hard to tell**

NOTE: This has implications for interpreting a null result!

F-value

$$F = \frac{Between\ Group\ Variability}{Within\ Group\ Variability} = \frac{\frac{SS_{between}}{Df_{between}}}{\frac{SS_{within}}{Df_{within}}} = \frac{SS_{between}}{Df_{between}} \times \frac{Df_{within}}{SS_{within}} = \frac{SS_{between}}{SS_{within}} \times \frac{Df_{within}}{Df_{between}}$$

SS = Sum of Squares

In case

$$SS_{within} = \sum (\overline{RT}_p - \overline{RT}_{g_p})^2$$

$$SS_{between} = \sum N_g \times (\overline{RT}_g - \overline{RT})^2$$

Hypothesis Testing

1. Can you express H0 in words?

Hypothesis Testing

1. Can you express H0 in words?
   - *We cannot say whether the observations derive from different "populations"*
   - *We cannot exclude that the observations are drawn from different distributions*

Hypothesis Testing

1. Can you express H0 in words?
   - *We cannot say whether the observations derive from different "populations"*
   - *We cannot exclude that the observations are drawn from different distributions*
2. Can you express H0 formally?

Hypothesis Testing

1. Can you express H0 in words?
   - *We cannot say whether the observations derive from different "populations"*
   - *We cannot exclude that the observations are drawn from different distributions*
2. Can you express H0 formally?

$$\hat{Y}_{pg} = \mu + \epsilon_{pg}$$

$$\epsilon_{pg} \sim N(0, \sigma^2)$$

Hypothesis Testing

1. Can you express H0 in words?
   - *We cannot say whether the observations derive from different "populations"*
   - *We cannot exclude that the observations are drawn from different distributions*
2. Can you express H0 formally?

$$\hat{Y}_{pg} = \mu + \epsilon_{pg}$$

$$\boxed{\epsilon_{pg} \sim N(0, \sigma^2)}$$

ANOVA assumption!

Linear Model

- H0 looks like a linear model, right?
  Indeed, ANOVA is a method **applied to** a linear model
- *F* has some similarities with R^2

$$F = \frac{SS_{between}}{SS_{within}} \times \frac{Df_{within}}{Df_{between}}$$

$$R^2 = 1 - \frac{SS_{residuals}}{SS_{total}}$$

Proportion of variance in the outcome captured by the predictor

370
360
350
340
330
320
RT [s]
congruent
incongruent
mixed
LM:
$\beta_{mixed} = \mu_{congruent} - \mu_{mixed}$
= Slope
ANOVA: $\mu_{congruent} - \mu_{mixed}$

Going Bayesian

- A linear model is a more flexible tool than and ANOVA (or any other tests)
- The switch between the two it’s quite easy
- The switch to a Bayesian approach is quite easy too
  - In terms of code
  - As for anything, some aspects require learning and adjusting, BUT…
  - The benefits in terms of interpretability and general practice outweigh the challenges

Going Bayesian

- Both Frequentist and Bayesian approaches use likelihoods
  - We'll see the similarity through code

Going Bayesian
